Abstract. We have investigated the two open clusters NGC 6192 and NGC 6451 for which widely different reddening values and thus ages and distances via Strömgren uvby photometry can be found in the literature. Our measurements allow us to disentangle the apparent discrepancies in the literature and to derive new accurate values. From appropriate calibrations we find that the overall abundance for NGC 6192 is about solar whereas a subsolar value for NGC 6451 was estimated. From two previous reported photometrically candidate CP stars, one within NGC 6192 shows Strömgren indices typical for a B8 Si star whereas the one in NGC 6451 is most probably a foreground G-type star.

Key words. stars: chemically peculiar – stars: early-type – techniques: photometric – open clusters and associations: general

1. Introduction

The two open clusters NGC 6192 and NGC 6451 are good examples of how different estimates of the interstellar reddening influence the derived distances and ages. For NGC 6451, Svoleopoulos (1966) lists a reddening $E(B - V) = 0.08$ mag whereas Kjeldsen & Frandsen (1991) give $E(B - V) = 0.70$ mag as the best value resulting in a difference of $560$ pc versus $2100$ pc and $5$ Gyr versus $0.2$ Gyr, respectively. The situation for NGC 6192 is almost identical.

We have observed these two open clusters within the Strömgren uvby system in order to derive the reddening as well as the overall metallicity. We have not tried to independently estimate the ages since no reliable isochrones within the Strömgren uvby system have been published so far. Since no $\beta$ measurements were made, the calibration of effective temperatures is not possible on solid grounds. However, ages have been derived in the literature for both clusters depending on the individual reddening values (Kjeldsen & Frandsen 1991).

Paunzen & Maitzen (2002) found one photometric CP candidate in each program cluster via $\Delta$ photometry (Maitzen 1976). We have investigated the Strömgren indices for these two objects in order to clarify their nature.

In the following two sections we will summarize the already published information about NGC 6192 and NGC 6451.

Unfortunately, no Strömgren photometry for these objects can be found in Hamuy et al. (1992, 1994) and Landolt (1992). For this purpose we used the measurements of the three standard stars L TT 377, L TT 1020 and L TT 9239 were observed. However, we have used the spectrophotometric measurements and the standard Strömgren u, b, y transmission curves (Crawford & Barnes 1970) to calculate “synthetic” photometric indices for these three standard stars. The small range of the color indices (e.g. <0.1 mag for b-y) makes any reliable calibration for the whole relevant color range (more than 1.2 mag; see Fig. 3) very problematic. However, we used the calculated photometric indices to derive absolute fluxes using the calibration of Gray (1998). He lists absolute flux calibrations for the Strömgren u, b, y bands on the basis of data from Vega. The data for our three standard stars are intrinsically consistent and a comparison with the results listed for the Johnson UBVRI by Hamuy et al. (1992, 1994) and Landolt (1992) shows an excellent agreement.

For the determination of the extinction coefficients we closely follow the approach described in Sung & Bessell (2000). For this purpose we used the measurements of the three standard stars at airmasses from 1.0 to 2.0 on the two different nights. The coefficients were found to be 0.48, 0.31, 0.18 and 0.11 for u, v, b and y, respectively.

For the calibration of the instrumental b - y, m1 and c1 values we used the following procedure. The observed CCD photometric B - V values for NGC 6192 (King 1987; Kjeldsen & Frandsen 1991) and NGC 6451 (Kjeldsen & Frandsen 1991) were transformed into b - y magnitudes using the correlations listed in Caldwell et al. (1993). These values served as a standard system for the calibration of our instrumental values. Figure 2 shows the (b - y)standard versus (b - y)instrument diagram with the available data for both open clusters. The line fits the data of the two clusters very well. Taking the calibrated b - y magnitudes, [m1], and [c1] indices were calculated using the absolute fluxes derived for the three standard stars as described above. Since these indices are not sensitive to reddening (Crawford & Mander 1966), the offsets of the instrumental m1 and c1 can be estimated. The y magnitudes were directly converted into standard Johnson V ones using the data of King (1987) and Kjeldsen & Frandsen (1991).

We find the following transformation for the instrumental magnitudes:

\[
V = -3.02(4) + 0.997(2) \cdot y,
\]

\[
b - y = -0.103(9) + 0.921(14) \cdot (b - y),
\]

\[
m_1 = -0.723(9) \cdot (m_1),
\]

\[
c_1 = +0.146(8) \cdot (c_1).
\]

These equations hold for the data of both open clusters.

3. Calibration into the standard photometric system

A very important point is the calibration of the observed photometric values to standard ones. For the determination of the extinction of the individual filters, three spectrophotometric standard stars LTT 377, LTT 1020 and LTT 9239 were observed. Spectrophotometric as well as broadband Johnson UBVRI photometry for these objects can be found in Hamuy et al. (1992, 1994) and Landolt (1992). Unfortunately, no Strömgren u, b, y measurements for these objects are available. However, we have used the spectrophotometric measurements and the standard Strömgren u, b, y indices were calculated using the absolute fluxes derived for the three standard stars as described above. Since these indices are not sensitive to reddening (Crawford & Mander 1966), the offsets of the instrumental m1 and c1 can be estimated. The y magnitudes were directly converted into standard Johnson V ones using the data of King (1987) and Kjeldsen & Frandsen (1991).

We find the following transformation for the instrumental magnitudes:

\[
V = -3.02(4) + 0.997(2) \cdot y,
\]

\[
b - y = -0.103(9) + 0.921(14) \cdot (b - y),
\]

\[
m_1 = -0.723(9) \cdot (m_1),
\]

\[
c_1 = +0.146(8) \cdot (c_1).
\]

These equations hold for the data of both open clusters.

4. Program cluster

In the following two sections we will summarize the already published information about NGC 6192 and NGC 6451.
4.1. NGC 6192
Kilambi & Fitzgerald (1983; photographic photometry) and King (1987; CCD photometry) reported a rather old age (1300 Myr) with a reddening of $E(B-V)=0.26$ mag and a distance of about 1000 pc from the Sun. Kjeldsen & Frandsen (1991; CCD photometry) on the other hand listed a reddening of $E(B-V)=0.68$ mag, an age of 89 Myr and a distance of about 1700 pc from the Sun. The sources of CCD photometry agree very well and have been used for our analysis.

Paunzen & Maitzen (2002) analysed all published photometric data and found that the age, reddening and distance modulus from Kjeldsen & Frandsen (1991) give the best fit. They also reported the detection of one photometric CP candidate (No. 54 according to King 1987; No. 86, Kjeldsen & Frandsen 1991) with $\Delta d = +0.030$ mag. From their photometry a spectral type of B8 Si and an absolute magnitude of $M_V = +0.0(2)$ mag was concluded.

4.2. NGC 6451
Paunzen & Maitzen (2002) investigated the discrepancies in the data published by Piatti et al. (1998) and Kjeldsen & Frandsen (1991) for this open cluster. Piatti et al. (1998) lists $E(B-V)=0.08$ mag whereas Kjeldsen & Frandsen (1991) give $E(B-V)=0.70$ mag as the best value. This results in a difference of 560 pc versus 2100 pc and 5 Gyr versus 0.2 Gyr, respectively. Since Piatti et al. (1998) calibrated their isochrones using the data for NGC 6451, we decided to observe this open cluster via Strömgren $uwb$ photometry.

5. Results
First we estimated the reddening of NGC 6192 and NGC 6451. Taking the standard relation of Philip & Egret (1980), the observed magnitudes were shifted accordingly. Figure 3 shows the $M_V$ versus $(b-y)_0$ diagrams. The reddening of both program clusters was found to be $E(b-y)_0=0.40(5)$ mag. This is well in line with the estimates of Kjeldsen & Frandsen (1991) and clearly contradicts the values listed by King (1987; NGC 6192) and Piatti et al. (1998; NGC 6451). For the distance modulus we find $(V_0-M_V)=11.40(10)$ and $12.15(10)$ resulting in a distance of 1900(100) as well as 2690(100) pc for NGC 6192 and NGC 6451, respectively. Our results agree within 1$\sigma$ (NGC 6192) and 3$\sigma$ (NGC 6451) with those of Kjeldsen & Frandsen (1991). Several red giants were clearly visible for NGC 6192 whereas several bright ($M_V>-2.5$ mag) non-members for NGC 6451 were detected. We have not estimated the ages of both open clusters since no isochrones for the Strömgren $uwb$ system are available. The only way would be the transformation of the $(b-y)_0$ magnitudes into effective temperature which is strongly dependent on (unavailable) $\beta$ measurements. However, the ages listed in the literature are compatible with those derived from a comparison with the isochrones given in Schulz et al. (2002). Table 2 lists all results deduced from our analysis.

The $M_V$ versus $(b-y)_0$ diagram for NGC 6451 shows a clustering of objects parallel to the main sequence at $0.4 \leq (b-y)_0 \leq 0.7$ and $+1.0 \leq M_V \leq -0.5$. We have investigated the location of these objects with respect to the field of NGC 6451 (Fig. 4). The placement of these stars is randomly distributed over the whole observed area ruling out a possible

Paunzen & Maitzen (2002) concluded that the $V$ magnitudes given by Piatti et al. (1998) are on average one magnitude too bright and thus the reddening, age and distance listed within this reference are probably incorrect. They refitted the data of Piatti et al. (1998) and found $E(B-V)=0.60$ mag, $(V-M_V)=13.90$ and an age of about 0.4 Gyr which is consistent with the results of Kjeldsen & Frandsen (1991).

Furthermore, Paunzen & Maitzen (2002) found one photometric CP candidate within the boundaries of NGC 6451.

![Fig. 2. $(b-y)_{\text{standard}}$ versus $(b-y)_{\text{instrumental}}$ diagram for our program clusters.](image)

inconsistency in the reduction process as well as a second, more distant, open cluster within the vicinity of NGC 6451. Since almost none of these objects are within the innermost boundaries of NGC 6451, we believe that the clustering found is a manifestation of the more distant field population.

As a next step, the overall metallicities for both open clusters was estimated. For this purpose the calibration of Nissen (1981) for stars cooler than F0 was taken. Since no $\beta$ measurements are available we used the standard relations of Crawford (1975) and Olsen (1984) to estimate them for the relevant temperature domain. Such a procedure has to be used with caution. Applying this method results in [Fe/H] = $-0.10(9)$ and $-0.34(8)$ for NGC 6192 and NGC 6451, respectively. The errors in brackets are the errors of the means. This seems to indicate that the metallicity for NGC 6451 is slightly subsolar.

Another method to calibrate metallicities for red giants is listed by Hilker (2000). This calibration is valid for objects with $0.5 < (b - y)_0 < 1.0$ mag. This fact together with the apparent uncertainty of the membership of objects for NGC 6451 seriously limits the significance of the derived values. Only two and five objects remain for NGC 6192 and NGC 6451, respectively, which results in errors as large as $\pm 0.5$ dex.

The investigation of the photometric candidate CP star in NGC 6192 (Paunzen & Maitzen 2002) further strengthens its chemically peculiar nature. We find $(b - y)_0 = -0.026$, $[m_1] = 0.202$, $[c_1] = 0.738$ and $M_V = 0.21$ mag which are typical for a B8 Si star (Cameron 1966).

The values for the apparent peculiar object in NGC 6451 are typical for an unreddened G-type star (Crawford & Mander 1966) and rule out a chemical peculiarity: $(b - y) = 0.651$, $[m_1] = 0.467$, $[c_1] = 0.233$ and $M_V = 3.85$ mag. This case shows the importance of further photometric or spectroscopic investigations of candidate CP stars.

6. Conclusions

We have presented Strömgren $uvby$ photometry for the young open clusters NGC 6192 (374 objects) and NGC 6451 (912 objects). For both open clusters, widely different reddening
values and thus distances and ages can be found in the literature. From our photometry we were able resolve these discrepancies and derive new accurate values. The overall metallicities were found to be about solar for NGC 6192 as well as slightly subsolar for NGC 6451 using the appropriate calibrations from the literature.

The chemically peculiar nature for one object of NGC 6192 was proven whereas one photometric CP candidate within NGC 6451 has to be rejected.
